

OPERATING-CHARACTERISTIC GUIDED DESIGN OF GROUP-SEQUENTIAL TRIALS

ANIKO SZABO

ABSTRACT. Group-sequential designs are commonly used for clinical trials to allow early stopping for efficacy or futility. While the design of a single-stage randomized trial is guided by a target power for an alternative hypothesis of interest, the addition of interim analyses is driven by technical choices that are less understandable for clinicians. For example, the commonly used Lan-DeMets methodology requires specification of the timing of analyses and error spending functions. Since the rationale and effect of these technical choices is often unclear, the operating characteristics of the final design are explored under various values of the parameter of interest, and the design is then adjusted until desired properties are obtained.

In this work we develop methods for constructing designs that achieve the desired operating characteristics without the need to specify error spending functions or the timing of analyses. Specifically, we consider designing a study for the mean difference θ of a normally distributed outcome with known variance. The null hypothesis $H_0 : \theta = \theta_0$ is tested versus $H_A : \theta = \theta_A$, with power π at a significance level α . The interim analyses are designed so that for a pre-specified sequence θ_{Ak} the study stops for efficacy at stage k with probability π if $\theta = \theta_{Ak}$. If stopping for futility is also considered, then the requirement to stop for futility at stage k with probability π_F if $\theta = \theta_{0k}$ for pre-specified sequence θ_{0k} can also be added. We show that under some monotonicity restrictions, such designs exist for any choice of the timing of interim analyses. Specific designs can be selected by imposing additional optimality requirements, such as minimizing the expected sample size under the target alternative θ_A , or the average sample size under a weighted selection of the alternatives.

1. SETUP AND NOTATIONS

All the calculations are set up assuming a setting with a normally distributed outcome with a known variance, but many common settings can be reduced to / approximated by this special case.

Let $X_i \sim N(\theta, \sigma^2)$ be a sequence of independent identically distributed measurements. We are designing a study to test the following hypotheses:

$$H_0 : \theta = \theta_0 \quad \text{versus} \quad H_A : \theta \geq \theta_0 \quad (1)$$

with type I error α and power π at a pre-specified value $\theta = \theta_A$.

The test statistic for H_0 based on n values is $Z(n) = (\bar{X}_n - \theta_0) \sqrt{n} / \sigma = \sqrt{\mathcal{I}_n}(\bar{X}_n - \theta_0)$, where $\mathcal{I}_n = [\sigma^2/n]^{-1}$ is the Fisher information after n observations. Then for any value of θ

$$Z(n) \sim N(\sqrt{\mathcal{I}_n}(\theta - \theta_0), 1), \quad (2)$$

and for $n_1 \leq n_2$

$$\text{Cov}(Z_{n_1}, Z_{n_2}) = \sqrt{\mathcal{I}_{n_1} / \mathcal{I}_{n_2}}. \quad (3)$$

This information-based formulation holds (approximately) for a variety of potential designs and outcomes, including two-arm randomized and cross-over studies with normal or binary outcomes.

The study will use a group-sequential design with K analyses, conducted at relative times $t_1, \dots, t_K = 1$. The k^{th} analysis will be conducted after $n_k = N \times t_k$ observations have been obtained, where N is the maximum sample size of the study. Based on the test statistic $Z_k = Z(n_k)$ at analysis $k = 1, \dots, K - 1$, the trial can be stopped early for efficacy (reject H_0) if $Z_k \geq u_k$, stopped early for futility (fail to reject H_0) if $Z_k \leq l_k$, or continued to the next stage. At the final, K^{th} analysis, H_0 would either be rejected if $Z_K \geq u_K = l_K$, or we would fail to reject H_0 otherwise. As a special case, setting $l_k = -\infty$ will result in a study when interim stopping for futility is not considered.

The decision boundaries $u_k, l_k, k = 1, \dots, K$, and the maximum information target (\sim sample size) \mathcal{I}_{\max} have to be selected so that the overall type I error and power of the study are maintained at their design

TABLE 1. Notations

| Characteristic | Notation | Event |
|--|-------------------|--|
| No or non-binding futility boundary | | |
| Rejection <i>at stage k</i> | \mathcal{R}_k | $\{Z_1 < u_1, \dots, Z_{k-1} < u_{k-1}, Z_k \geq u_k\}$ |
| Continuation <i>at stage k</i> | \mathcal{C}_k | $\{Z_1 < u_1, \dots, Z_{i-1} < u_{k-1}, Z_k < u_k\}$ |
| Non-binding futility boundary | | |
| Acceptance <i>at stage k</i> | \mathcal{A}_k | $\{l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, Z_i \leq l_k\}$ |
| Binding futility boundary | | |
| Rejection <i>at stage k</i> | \mathcal{R}_k^* | $\{l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, Z_k \geq u_k\}$ |
| Continuation <i>at stage k</i> | \mathcal{C}_k^* | $\{l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, l_k < Z_k < u_k\}$ |
| Acceptance <i>at stage k</i> | \mathcal{A}_k | $\{l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, Z_i \leq l_k\}$ |

TABLE 2. Target operating characteristics

| Characteristic | Event | θ | Probability target |
|--|-----------------------------------|---------------|--------------------|
| No or non-binding futility boundary | | | |
| Overall type I error | $\bigcup_{i=1}^K \mathcal{R}_i$ | θ_0 | $\leq \alpha$ |
| Overall power | $\bigcup_{i=1}^K \mathcal{R}_i$ | θ_A | $\geq \pi$ |
| Stop by stage k for efficacy | $\bigcup_{i=1}^k \mathcal{R}_i$ | θ_{Ak} | $\geq \pi_E$ |
| Non-binding futility boundary | | | |
| Stop by stage k for futility | $\bigcup_{i=1}^k \mathcal{A}_i$ | θ_{0k} | $\geq \pi_F$ |
| Binding futility boundary | | | |
| Overall type I error | $\bigcup_{i=1}^K \mathcal{R}_i^*$ | θ_0 | $\leq \alpha$ |
| Overall power | $\bigcup_{i=1}^K \mathcal{R}_i^*$ | θ_A | $\geq \pi$ |
| Stop by stage k for efficacy | $\bigcup_{i=1}^k \mathcal{R}_i^*$ | θ_{Ak} | $\geq \pi_E$ |
| Stop by stage k for futility | $\bigcup_{i=1}^k \mathcal{A}_i$ | θ_{0k} | $\geq \pi_F$ |

values, but there are many valid choices. In this *operating characteristic driven* approach we propose to select the boundaries based on the cumulative probabilities of stopping for efficacy or futility at each stage.

Theorem 1. *A design satisfying the operating characteristic requirements of Table 2 exists, if the following conditions are satisfied:*

- C1. $\pi_E \leq \pi$
- C2. $\theta_{A1} \geq \theta_{A2} \geq \dots \geq \theta_{A,K-1} \geq \theta_A$

Additionally, if a futility boundary is needed:

- C3. $\pi_F \leq 1 - \alpha$
- C4. $\theta_{01} \leq \theta_{02} \leq \dots \leq \theta_{0,K-1} \leq \theta_0$

Proof. We will consider the cases of no, non-binding, and binding futility boundaries separately.

I. no futility boundary We will use proof by induction over the number of stages K . When $K = 1$, only the overall type I error and power need to be considered, and the well-known single-stage design achieving the overall information

$$\mathcal{I}_{\text{fix}} = \frac{(z_\alpha + z_{1-\beta})^2}{(\theta_A - \theta_0)^2} \quad (4)$$

will satisfy the requirements with $u_K = z_\alpha$.

Now suppose we can construct the desired design for $K - 1$ stages, and we try to add an additional stage. For the first $K - 1$ stages select the boundary u_1, \dots, u_{K-1} and information times $\mathcal{I}_{n_1}, \dots, \mathcal{I}_{n_{K-1}}$ to achieve over these $K - 1$ stages stage-specific stopping probabilities π_E at $\theta_{A1}, \dots, \theta_A, K - 2$, overall power π_E at $\theta_{A, K-1}$, and overall type I error $\alpha_{K-1} = \alpha - \Delta\alpha_K$, where $0 < \Delta\alpha_K < \alpha$ is an arbitrary value. With these choices, the requirements for all the stage-specific probabilities for the K -stage design are satisfied. We need to select I_{n_K} and u_K to satisfy the overall power and type I error restrictions.

Consider the function $a(u | \mathcal{I}_N) = \Pr(\{\bigcup_{i=1}^{K-1} \mathcal{R}_i\} \cup \{Z_1 < u_1, \dots, Z_{K-1} < u_{K-1}, Z(N) \geq u\} | \theta_0)$, that gives the type I error if the boundary is set at u for the last stage for any given $I_N > I_{n_{K-1}}$. Under H_0 , $Z(N) \sim N(0, 1)$, so $a(z_\alpha | \mathcal{I}_N) \geq \alpha$. On the other hand, $a(\infty | \mathcal{I}_N) = \alpha - \Delta\alpha_K < \alpha$ by the design of the first $K - 1$ stages. Since a is monotone in u , for any I_N there exists a cutoff $u_K(\mathcal{I}_N)$ for which $a(u_K(\mathcal{I}_N)) = \alpha$, ie for which the overall type I error is maintained at the desired level.

Next consider the function $b(\mathcal{I}_N) = \Pr(\{\bigcup_{i=1}^{K-1} \mathcal{R}_i\} \cup \{Z_1 < u_1, \dots, Z_{K-1} < u_{K-1}, Z(N) \geq u_K(\mathcal{I}_N) | \theta_A)$ that gives the power to reject H_0 if the final analysis is set at information $\mathcal{I}_N > I_{n_{K-1}}$. If $b(\mathcal{I}_{K-1}) \geq \pi$, then we can set $\mathcal{I}_N = \mathcal{I}_{K-1}$. Otherwise, note that $b(\infty) = 1$, and b is monotone in \mathcal{I}_N . Thus we can select a value n_K such that $b(\mathcal{I}_{n_K}) = \pi$, which will provide the desired design.

II. Non-binding futility boundary The overall power, type I error, and stage-specific efficacy power requirements do not depend on a non-binding futility boundary, so we can start with a design constructed without a futility boundary. We then need to calculate the lower bounds l_k to satisfy the futility stopping probabilities. For stage 1, we need $\Pr(Z_1 < l_1 | \theta_{01}) = \pi_F$, where $Z_1 \sim N(\sqrt{I_1}(\theta_{01} - \theta_0), 1)$. Thus $l_1 = z_{1-\pi_F} + \sqrt{I_1}(\theta_{01} - \theta_0)$ satisfies the target power. Given conditions C3-C4, $l_1 \leq z_\alpha$, while $u_1 \geq z_\alpha$, so $l_1 \leq u_1$.

At stage k , consider the function $c(l) = \Pr(l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, Z_k < l | \theta_{0k})$. Since $\theta_{0k} \leq \theta_0$, $c(z_\alpha) \geq 1 - \alpha \geq \pi_F$, while $c(-\infty) = 0$, so a value l_k can be selected for which $c(l_k) = \pi_F$.

III. Binding futility boundary The construction follows the induction-based approach of part I. During the inductive step in addition to I_K and u_K , we need to find a value for l_{K-1} that will satisfy the futility boundary restriction. This can be done as shown in part II before proceeding with the selection of the parameters of the last stage. A potential complication compared to the efficacy-only situation, is that by adding l_{K-1} we might overspend the type II error, $\Pr(\bigcup_{i=1}^{K-1} \mathcal{A}_i | \theta_A) > 1 - \pi$. In this case we would not be able to select a value for \mathcal{I}_N such that $b^*(\mathcal{I}_N) \geq \pi$, because even $b^*(\infty) < \pi$. One of the possible solutions is to adjust the timing of the $(K - 1)$ st stage to reduce its beta-spending. As \mathcal{I}_{K-1} is increased beyond the value that provided power π_E at significance level $\alpha - \Delta\alpha_K$, if we maintain the significance level, $P(\mathcal{R}_{K-1}^* | \theta_{A, K-1})$ will increase, so the power will be maintained. However $\Pr(\mathcal{A}_{K-1} | \theta_A)$ will decrease, so we can find a value of I_{K-1} for which $\Pr(\bigcup_{i=1}^{K-1} \mathcal{A}_i | \theta_A) = 1 - \pi$. Starting from this modified design with $K - 1$ stages, we can now construct the required K -stage design. □

In the proof of the theorem we have obtained the following uniqueness result:

Corollary 1. *Under the assumptions of Theorem 1, an alpha-spending sequence $\Delta\alpha_k > 0$, $k = 1, \dots, K$ such that $\sum_{k=1}^K \Delta\alpha_k = \alpha$ uniquely determines a design with the required operating characteristics.*

2. MAIN FUNCTION: CALCULATE DESIGN

We want to set up the design as a function of `n.fix`, the sample size required for the single-stage study, and report the results in terms of sample size. Since $\mathcal{I} \propto n$, we can do the calculations in terms of information, but then rescale everything as

$$n = \frac{\mathcal{I}}{\mathcal{I}_{fix}} n_{fix}. \quad (5)$$

The second modification from the theoretical development is that instead of standardized effect sizes we will use the relative size of the interim effects, scaling everything to $\theta_A - \theta_0$:

$$r_k^E = \frac{\theta_{Ak} - \theta_0}{\theta_A - \theta_0},$$

$$r_k^F = \frac{\theta_{0k} - \theta_0}{\theta_A - \theta_0}.$$

Keeping the fold-changes r_k constant, a C -fold decrease in the effect size $\theta_A - \theta_0$ is equivalent to a C -fold increase in the required sample size/information. So we can build the design assuming $\theta_0 = 0$ and $\theta_A = 1$, and then adjust the final sample size as

$$n(\theta_0, \theta_1) = \frac{n(0, 1)}{(\theta_A - \theta_0)^2}. \quad (6)$$

Putting together equations 4, 5, and 6, we have

$$n(\theta_0, \theta_1) = \frac{\mathcal{I}(0, 1)}{(z_\alpha + z_{1-\beta})^2} n_{fix}, \quad (7)$$

where $\mathcal{I}(0, 1)$ is computed assuming $\theta_0 = 0$ and $\theta_A = 1$.

We define a spending function with values equal to the optimal α_k at the optimal time-points, and is linearly interpolated between them. For the lower boundary we need to compute the actual β -spending first. The `sfLinear` spending function expects a vector of parameters in which the first half defines the time-points and the second half the corresponding values scaled as the proportion of total error to be spent.

< Create custom spending functions 8a > \equiv

```

upper_sf <- gsDesign::sfLinear
upper_par <- c(timing, cumsum(x$spending)/x$sig.level)

if (x$futility.type != "none"){
  probs <- gsDesign::gsProbability(k=x$n.stages, n.l=x$info, a=x$lower, b=x$upper, theta=c(0,1))
  beta.spend <- cumsum(probs$lower$prob[,2])
  lower_par <- c(timing, beta.spend/tail(beta.spend,1))
  lower_sf <- gsDesign::sfLinear
} else {
  lower_sf <- NULL
  lower_par <- NULL
}

```

2.2. Direct optimization.

< Find optimal design using direct search 8b > \equiv

< Define optimization function 9a >

```

if (n.stages == 2){
  oo <- optimize(.cp, interval=c(-5,5))

  y.res <- oo$minimum
  alpha.seq <- sig.level * exp(c(y.res,0)) / sum(exp(c(y.res,0)))
}

```

```

} else {
  y.start <- -log(seq(n.stages, 2, by=-1))

  oo <- optim(y.start, fn=.cp, method="Nelder-Mead")

  y.res <- oo$par
  alpha.seq <- sig.level * exp(c(y.res,0)) / sum(exp(c(y.res,0)))
}

```

Fragment referenced in [4](#).

Using the `calc.bounds` function, we can construct a design matching all the type I error/power requirements given a sequence of stage-specific positive alpha-spending values $\Delta\alpha_k$ that add up to α . To allow unconstrained optimization, we can reparametrize it using the multinomial logit:

$$y_k = \log \frac{\Delta\alpha_k}{\Delta\alpha_K}, \quad k = 1, \dots, K-1,$$

with reverse transition

$$\Delta\alpha_k = \frac{\alpha e^{y_k}}{\sum_{i=1}^K e^{y_i}}, \quad k = 1, \dots, K,$$

where $y_K := 0$.

⟨ Define optimization function 9a ⟩ \equiv

```

.cp <- function(y.vec){

  y <- c(y.vec, 0) # add y_K
  alpha.seq <- sig.level * exp(y) / sum(exp(y))

  resc <- calc.bounds(x=res, alpha.seq = alpha.seq)
  dp <- oc(rescp, r_EN=r_EN, r_EN.w=r_EN.w)
  Q <- dp$ave.EN
  Q
}

```

Fragment referenced in [8b](#).

Uses: `calc.bounds` [13b](#), `oc` [10c](#).

2.3. Recursive optimization.

⟨ Find optimal design using recursive search 9b ⟩ \equiv

```

⟨ Define recursive optimization function 9c ⟩
  alpha.seq <- .opt.spend(x=res)

```

Fragment referenced in [4](#).

The recursive optimization also implements the construction process in the proof of Theorem [1](#), but will select the optimal $\Delta\alpha_K$ when adding the last stage.

For the first $K-1$ stages we will select the boundary u_1, \dots, u_{K-1} and information times $\mathcal{I}_{n_1}, \dots, \mathcal{I}_{n_{K-1}}$ to achieve over these $K-1$ stages stage-specific stopping probabilities π_E at $\theta_{A1}, \dots, \theta_{A,K-2}$, overall power π_E at $\theta_{A,K-1}$, and overall type I error $\alpha_{K-1} = \alpha - \Delta\alpha_K$.

The `.opt.spend` function will return the optimal alpha-spending sequence.

⟨ Define recursive optimization function 9c ⟩ \equiv

```
.opt.spend <- function(x){
  if (x$n.stages == 1){
    return(x$sig.level) # we spend it all
  }
}
```

Find optimal DeltaAlpha to spend 10a

◇

Fragment referenced in 9b.

The search for $0 < \Delta\alpha_K \leq \alpha$ will be parametrized via $y = \log(\Delta\alpha_K/\alpha)$ with $y \leq 0$ to restrict it to the correct range, and better spread out small values.

Find optimal DeltaAlpha to spend 10a \equiv

< Define lower bound exceedance 16c >
< Define function to find l 17a >

```

◇

Fragment referenced in 13b.

4.1. Upper bound exceedance. The functions a and b in the proof of Theorem 1 have a similar form, so we will define the following function:

$$e(u | \mathcal{I}) = Pr\left(\bigcup_{i=1}^{k-1} \{l_1 < Z_1 < u_1, \dots, l_{i-1} < Z_{i-1} < u_{i-1}, Z_i \geq u_i\} \bigcup \{l_1 < Z_1 < u_1, \dots, l_{k-1} < Z_{k-1} < u_{k-1}, Z(\mathcal{I}) \geq u\} \mid \theta\right).$$

If l_i is set to $-\infty$, then that is equivalent to not having a lower boundary. We will need to solve equations of the form $e(u) = c$, so we will actually define a function for the difference of the LHS and RHS.

⟨ Define upper bound exceedance 15a ⟩ \equiv

```
exc <- function(u, I, stage, theta, target){
  gg <- gsDesign::gsProbability(k=stage,
                                theta=theta,
                                n.I = c(head(ivec, stage-1), I),
                                a = c(head(lb, stage-1), -20),
                                b = c(head(ub, stage-1), u))
  sum(gg$upper$prob[1:stage]) - target
}
```

◇

Fragment referenced in 14c.

To find $u(I)$ we need to solve $a(u|\mathcal{I}) = \sum_{i=1}^k \Delta\alpha_i = \tilde{\alpha}_k$. Since $a(z_\alpha | \mathcal{I}_N) \geq \alpha$ [NOTE: I AM NOT SURE ABOUT THAT] and $a(\infty|\mathcal{I}_N) = \tilde{\alpha}_{k-1}$, the solution for fixed \mathcal{I}_N is between z_α and 20 (which is essentially ∞).

⟨ Define function to find $u(I)$ 15b ⟩ \equiv

```
uI <- function(I, stage){
  res <- uniroot(exc, interval=c(-20, 20),
                 I = I, stage=stage, theta=0, target = alpha.cum[stage],
                 extendInt = "downX")
  res$root
}
```

◇

Fragment referenced in 14c.

4.2. Construct next stage.

⟨ Construct next stage 15c ⟩ \equiv

```
⟨ Determine target power and alternatives 16a ⟩
⟨ Find lower bound for previous stage 17b ⟩
⟨ Find I for next stage 16b ⟩
```

◇

Fragment referenced in 13b.

To find I_k , we need to solve $b(\mathcal{I}) = \pi_E$, if $k < K$ and $= \pi$ for $k = K$.

$\langle \text{Determine target power and alternatives 16a} \rangle \equiv$

```
if (k == x$n.stages){
  power.target <- x$power
} else {
  power.target <- x$power.efficacy
}
.th <- x$rE.seq[k]
```

◇

Fragment referenced in [15c](#).

Note that $b(I_{k-1}) \leq \pi_E$ and $b(\mathcal{I}_{fix}(\theta_{Ak} - \theta_0, \tilde{\alpha}_k, \pi_E)) \leq \pi_E$, we can start the search at the maximum of these two values.

$\langle \text{Find } I \text{ for next stage 16b} \rangle \equiv$

```
exc_i <- function(ii)exc(uI(ii, k), ii, stage=k, theta=.th,
                        target = power.target)

minI <- max(ztest.I(delta = .th, power=power.target, sig.level=alpha.cum[k]),
            ivec[k-1])
curr.exc <- exc_i(minI)

if (curr.exc > 0){
  # already past target power
  ivec[k] <- minI
  ub[k] <- lb[k] <- uI(minI, k)
} else {
  resI <- uniroot(exc_i, interval=c(minI, 2*minI), extendInt = "upX")
  ivec[k] <- resI$root
  ub[k] <- lb[k] <- uI(resI$root, k)
}
◇
```

Fragment referenced in [15c](#).

Uses: [ztest.I 18a](#).

4.3. Add lower bound. The lower bound will usually be computed only when the information and upper bound for a stage has been determined. We will allow for vectorization over **theta** and **target**.

$\langle \text{Define lower bound exceedance 16c} \rangle \equiv$

```
exc_low <- function(l, stage, theta, target, I=ivec[stage]){
  gg <- gsDesign::gsProbability(k=stage,
                                theta=theta,
                                n.I =c(head(ivec, stage-1), I),
                                a = c(head(lb, stage-1), 1),
                                b = ub[1:stage])
  #lower$prob has rows by stage and columns by theta
  colSums(gg$lower$prob[1:stage, ,drop=FALSE]) - target
}
◇
```

Fragment referenced in [14c](#).

⟨ Define function to find l 17a ⟩ ≡

```
lI <- function(stage, theta, I=ivec[stage]){
  res <- uniroot(exc_low, interval=c(-20, qnorm(x$sig.level, lower.tail=FALSE)),
    stage=stage, theta=theta, target = x$power.futility, I=I,
    extendInt = "upX")
  res$root
}
```

Fragment referenced in 14c.

We need to find the lower bound for stage $k-1$, before computing the size of the next stage. If the boundary is not binding, we need to overwrite $l_k := u_k$ that was indicating the “last” stage so far to $l_k = -\infty$.

⟨ Find lower bound for previous stage 17b ⟩ ≡

```
if (x$futility.type == "binding" | x$futility.type=="non-binding"){
  lb[k-1] <- lI(stage=k-1, theta=x$rF.seq[k-1])
  if (x$futility.type == "binding"){
    ⟨ Check beta-spending and adjust previous stage if needed 17c ⟩
  }
} else {
  lb[k-1] <- -20
}
```

Fragment referenced in 15c.

With a binding boundary it is possible that the addition of l_{K-1} overspends the type II error under θ_{Ak} , and the target power for the next stage is not achievable anymore. More generally, the type II error could be overspent for any $\theta_{Aj}, j \geq k$. In this case, the information for the $(K-1)$ st stage needs to be increased. Due to the monotonicity of θ_{Aj} , we only need to monitor type II error spending under θ_A . Specifically, we will ensure that each stage k has at least $\beta_{min}(K-k+1)$ type II error available for a small value of β_{min} . Since `uniroot` solve with a tolerance of `.Machine$double.eps`^{0.25}, we need to set β_{min} above that.

⟨ Check beta-spending and adjust previous stage if needed 17c ⟩ ≡

```
beta.min <- .Machine$double.eps^0.25
.beta.limit <- beta.min * (x$n.stages - k + 1)
typeII.overspent <- exc_low(lb[k-1], stage=k-1, theta=1, target = 1 - x$power - .beta.limit)
if (typeII.overspent > 0){
  exc_low_i <- function(ii)
    exc_low(lI(I=ii, theta=x$rF.seq[k-1], stage=k-1), ii, stage=k-1, theta=1,
      target = 1 - x$power - .beta.limit)
  if (exc_low_i(1e6) > 0) browser()
  resI_low <- uniroot(exc_low_i, interval=c(ivec[k-1], 2*ivec[k-1]), extendInt = "downX")
  ivec[k-1] <- resI_low$root
  ub[k-1] <- uI(I = resI_low$root, stage = k-1)
  lb[k-1] <- lI(I = resI_low$root, theta = x$rF.seq[k-1], stage = k-1)
}
```

Fragment referenced in 17b.

For a non-binding boundary, the lower bound is added only after the entire upper bound has been calculated.

⟨ Add non-binding lower bound 17d ⟩ ≡

```
for (k in 1:(x$n.stages-1)){
```

```

    lb[k] <- lI(stage=k, theta=x$rF.seq[k])
  }
  ◇

```
